

| Project Jobs | Operations Jobs |
|--------------|-----------------|
| 470 | 250 |

New Jersey has the opportunity to create an annual average of up to **470 project jobs** over a 15-year period and **250 ongoing operations jobs** through the deployment of carbon capture at two industrial and power facilities. Developing carbon dioxide (CO₂) capture, transport and storage infrastructure at these facilities could generate up to **\$2 billion in private investment** and capture **four million metric tons** of CO₂ every year.

CREATING JOBS & CAPTURING CARBON

Carbon capture is essential to meeting mid-century emissions reduction goals while retaining and growing a domestic base of high-wage energy, industrial, and manufacturing jobs. Carbon capture retrofits require facilities to be outfitted with technologies to remove the CO₂ and ensure it is transport ready. The type of technology used is dependent on the type of plant and varies across industry and facilities. There are jobs associated with the equipment, materials (e.g. cement and steel), engineering, and labor required to install the capture technology, as well as ongoing jobs to operate and maintain the retrofits. These are referred to as **project jobs** and **operations jobs**.

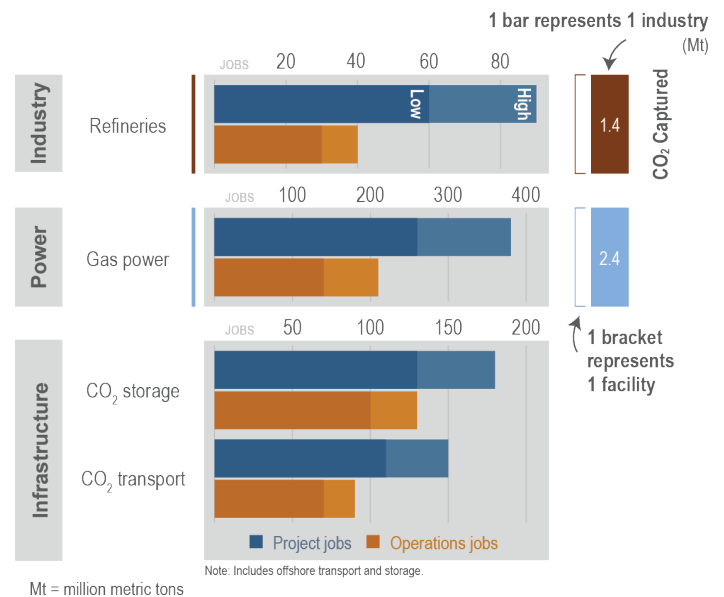

METHODOLOGY

Rhodium Group performed an economic analysis based on the Regional Carbon Capture Deployment Initiative's Near- and Medium-Term capture potential scenario. The Rhodium analysis quantifies the economic impact and employment opportunities of carbon capture retrofit projects by deploying state-specific data in the IMPLAN economic model. The analytical results measure the impact of project investment and operation costs through expected annual jobs. Average annual project jobs were calculated assuming deployment of all projects over a 15-year period. The jobs reported are in-state jobs, directly associated with carbon capture retrofits. They do not include other jobs at the facilities, nor indirect and induced jobs.

RESULTS

New Jersey's one industrial refinery holds valuable potential for emissions reductions and job creation with carbon capture retrofit, with the potential to create an annual average of up to 90 project jobs and 40 ongoing operations jobs while capturing 1.4 million metric tons of CO₂ per year. New Jersey also has a gas power facility with the ability to create an annual average of up to 380 project jobs and 210 ongoing operations jobs and capture 2.4 million metric tons of CO₂ with carbon capture retrofit. The development of transport infrastructure would create an annual average of up to 150 project jobs and 90 ongoing operations jobs. The development of storage infrastructure would create an annual average of up to 180 project jobs and 130 ongoing operations jobs.

ANNUAL PROJECT AND OPERATIONS JOBS

This figure depicts the low and high range of estimated annual average project jobs, transport infrastructure jobs, and ongoing operations jobs that could be created through carbon capture retrofits at industrial and power facilities in New Jersey. The potential amount of CO₂ captured and the number of potential near- or medium-term capture facilities in each industry are shown above.
